3- Carnegie Mellon University, Pittsburgh, USA

Over the last few years there have been important efforts to improve the rigor, unity and operationality of Design theories. This work builds on the multiple (but scattered) theoretical proposals in recent decades: General Design Theory and Axiomatic Design in the 80s, Coupled Design Process in the 90s, Infused Design and C-K Theory in the 2000s. These theories echoed issues in practices (new design tools, innovative design,...) and the advancements of other sciences (artificial intelligence, set theory, engineering sciences,...). They contributed to ground a research community that has been reinvigorated by several initiatives¹. This special issue aims at a better understanding of the early efforts in design theory, as well as showcasing promising contemporary research in the field. Of course such a collection of papers cannot be exhaustive - it should be seen as a first attempt, to be followed and augmented by other publications. Nevertheless, the critical ambition of this issue is *to better identify the object of design theory and to begin to overcome shortcomings of their current conceptions*.

The four questions of Design Theory,

Design theory is a very demanding research field. Design is an incredibly complex and sophisticated human activity that goes beyond animal design (see Orang Utan Nest Building - (van Casteren et al. 2012)) and “unselfconscious design” (Alexander 1964). Self conscious design contains many well-known activities (decision making, optimization, modeling, knowledge production, prototyping, ideation, evaluation, etc). However, it cannot be reduced to any one of them or all of these activities (e.g.: decisions are made in design, but design is more than decision making). Thus design theory is not about modeling everything that one can find in a design practice, its goal is to precisely address issues that are beyond the scope of the classical models that accompany its constituent activities (decision making, prescriptive models, hypothetic-deductive model and others). The questions this goal raises is of course: What, then, are the core phenomena of Design? Is Design driven by novelty, continuous improvement, creativity, imagination?

Design theorists realized that we cannot expect to answer these questions with ordinary language, and that this investigation will thus require high level formal languages and models. This is an ongoing quest: many issues remain in the elaboration of these fledgling models, and their validity and veracity are under critical scrutiny. In February 2013, at the 6th Paris Workshop of the Design Theory SIG of the Design Society, Armand Hatchuel and Yoram Reich made a synthesis of five years of works of the SIG and mentioned *four main difficulties* for research on Design Theory:

1. no self evident unity of the design theory field,
2. multiple paradigm shifts that threaten the specificity of design,
3. the fragmentation of the design professions and
4. the limits of empirical research.

¹ See in particular the Special Interest Group on Design Theory, launched in 2008 on the suggestion of the Board of the Design Society

The lead questions in this editorial are: how did the papers presented in this special issue deal with these difficulties? And how do they open new paths for research in design theory? We first elaborate and detail these four challenges before formulating our perspective on the papers.

1- No self-evident unity of the design theory field

There are already many models for design theories. For design theories might be as old as (self conscious) design itself. As early as 20 BC, in his *De Architectura* Vitruvius proposed an abstract definition of architecture that helped the architects to deal with the variety of knowledge and go beyond the specificity of each building – architecture “depends on Order, Arrangement, Eurythmy, Symmetry, Propriety, and Economy” (book 1, chapter 2). Following the rapid development of Mechanical engineering in the 19th century, the recognition of Design theories as crucial tools led to help teach machine design and to organize design work in industry. Then, as the scope of engineering sciences increased very rapidly, each engineering revolution (chemical, electrical, electronics, software...) was accompanied by the development of its own appropriate design tools and theories. It is primarily after WW2 that the idea of a Design theory that would be common to architecture and engineering disciplines emerged. Following the Vitruvius approach, one of the earliest drive at systematizing design was undertaken in the first conference on Systematic Design Methods in 1960's as in the method of analysis, synthesis and evaluation (ASE) (Jones and Thornley 1963). These efforts were further elaborated as theory of technical systems (Hubka and Eder 1988) and its more recent advances, FBS (Gero 1990; Dorst and Vermaas 2005), General Design Theory (Yoshikawa 1981; Reich 1995), Axiomatic Design (Suh 1990), Coupled Design Process (Braha and Reich 2003), Infused Design (Shai and Reich 2004) or C-K theory (Hatchuel and Weil 2009). But if one looks beyond the similarities in these domain-independent theories, are they complementary or perhaps contradictory? Do they share common roots? To what extent are the theories limited by the (implicit) goals that motivated their creation? Are they reasonably comprehensive in their approach to design? These questions remain open and critical.

2) Multiple paradigm shifts that threat the specificity of design

Moreover the efforts towards unity of the field are continuously *shaken by changing paradigms in the analysis of design*. In the 1960s-70s, the temptation was to assimilate design to decision science, cybernetics and information theory – one major attempt was made by Simon. This resulted in his “sciences of the artificial” that was rooted in the concept of a general problem solver (Simon 1969). During the 70-80's there was a move towards creating a universal design method that was akin to the scientific method (Cross 1984). Overlapping with this move, in 1980s-1990s Artificial Intelligence (more generally computational models of design), Computer Aided Design systems and Systems theory were meant to be the core of design theory². In 1990s-2000s situated cognition, communication and agent-based systems were the new potential roots for design theory; and today advances in neuroscience threaten to overwhelm design theory. The strength and health of the design theory appears in the capacity of researchers to show how design theory can learn from all these approaches, proposing integrated models that go beyond these paradigms and offer a rigorous, meaningful and autonomous corpus that fits the nature of design. For instance it was underlined and demonstrated that design was more than “decision making”, even if a “bounded rational choice” (Hatchuel 2002; Dorst 2006), and this critic led to propose that design was rather an “expandable rationality” (Hatchuel 2002). The papers of this special issue show that this

² For comprehensive map of design methods and theories as of 1992 see (Konda et al. 1991)

autonomous, rigorous corpus has grown over time and is now forming a basis to dialog with other disciplines – mathematics, logics, engineering sciences and cognition.

3) The fragmentation of design professions

Surprisingly, design professionals are not the ones leading the effort to create a disciplinary foundation. In spite for efforts of by design research societies³ to bring them together through a joint conference, efforts in design theory are still fragmented. The contrasted figures of architects, engineers and industrial designers use different journals, rely on different epistemologies, and connect to different disciplines. This presents a huge challenge for design theory: how to overcome the professional traditions to uncover the universality of design.

Beyond the scientific issue, this is also an important social and political issue: showing the universality of design leads also to reveal its presence today in all aspects of social, organizational and political life, where decision making more and more appears secondary and determined by the critical issue of generating the set of alternatives and organizing the investigations to expand it.

4) The limits of empirical research

Finally, design theory has to overcome a fourth obstacle that focuses on empirical research and its contribution to design theory. Empirical research is necessary for design theory. – For example to test hypotheses or to suggest new phenomena to be modeled. There has always been strong relationships between empirical and theoretical approaches in design theory – with complex interdependences, as suggested by the models of design processes of (Finger and Dixon 1989) or by the historical analysis of pendulum movements between “art” and “science” in design methods (Heymann 2005). More recently, many empirical approaches have been used in the community (in the US and in Europe). As shown in (Heymann 2005) or (Ehrlenspiel 1995), they led to enriching the phenomenology of collective design. A sample of the range and focus of empirical studies in design from studying the design process to support design process across can be seen in (Subrahmanian et. al, 2000). But on the whole these studies do not address the problem of a formal theoretical unity. One of the challenges of design theory today consists in providing formal frameworks that lead to testable hypothesis, and to build the relevant instruments (protocols, observation techniques, tasks analysis and others) to empirically analyze design practices at this fundamental level. Research in design theory should be anchored in an interplay between formal models and empirical studies.

Consolidating research on design theory

In a nutshell, these are the four challenges to be overcome by the papers in this special issue: . How did the papers travel this complex territory?

1- Relating design theories to each other

Many of the papers of the special issue study multiple design theories and compare them (e.g. Parameter Analysis and systematic design in Kroll, C-K theory and forcing in Hatchuel et al., C-K theory and Infused Design in Shai et al., C-K and systematic Design in Le Masson & Weil). These comparisons can be fruitful:

- a) they reveal hidden aspects and critical issues for design theory: the logic of “holes” in knowledge as departure point for design (Shai et al.), the logic of unknown to be

³ The conference held every year by International association of Design Research Societies(IASDR) is such an attempt.

differentiated from the logic of the known (Le Masson and Weil), and more generally, the elements of an ontology of design (Hatchuel et al.).

- b) these comparisons underline the interest of powerful formal design theories to analyze specific models and methods, helping to characterize their efficiency and limits. For instance, Le Masson & Weil's paper underlines that systematic design is relevant for rule-based design situations, Shai et al. illustrate the potential of infused design when knowledge is highly structured and connected, Kroll shows that Parameter Analysis has a strong value when designers want to renew design rules. These results pave the way to a contingent approach in design theory, to an understanding of the "ecology of theories and methods".

2- Overcoming paradigms that shade the specificity of design

Constructivism in design (Kazakçi), engineering science and design (Le Masson & Weil), creativity and scientific discovery (Kroll), ideation (Taura), combinatorics (Hatchuel et al., Kroll) are discussed in this special issue.

- a) The discussion of these paradigms brings out the specificity of design. In Kroll, Le Masson and Weil, and Shai et al. we understand that design is more than engineering science. Taura and Nagai and Shai et al. demonstrate that design is more than ideation and creativity. We glean from Kazakçi, design as more than constructivism and in Taura & Nagai, Hatchuel et al. and Le Masson & Weil that it is more than combinatorics.
- b) Moreover it helps to enrich the paradigms themselves: Kazakçi proposes an extended view of constructivism, imaginative constructivism, Taura & Nagai a concept generation process relying on "dissimilarity recognition", Kroll, Shai et al., Le Masson & Weil and Hatchuel et al. focus on understanding how the dynamics of engineering sciences is based on design reasoning.

3- Bridging the gap between professions

The papers in the special issues dialog with multiple disciplines: with intuitionist mathematics (Kazakçi), with set theory (Hatchuel et al.), with orders in science (Shai et al.), with engineering science (Le Masson & Weil), with creativity (Taura & Nagai). They tend to underline their design logic in each discipline, and strong similarities between the different fields. For instance discovery in science (Shai et al.) and concept generation in more artistic domains (Taura & Nagai), or design of engineering objects and design in mathematics (Hatchuel et al.) tend to follow similar or complementary traits of design – recognition of the unknown, propagation of the concept based on available knowledge and generation of new concepts - even if the knowledge structures are apparently very different (mathematical models for Forcing in Hatchuel et al, engineering sciences for Infused Design in Shai et al., semantic models for concept generation in Taura & Nagai,...). The models proposed and used contribute to uncover the deep convergence of reasoning used by engineers, scientists or artists.

4- Theory-driven empirical research

Many of the papers use empirical material (see Kroll, Taura & Nagai or Shai et al.; Le Masson & Weil refer rather to historical empirical cases). Nevertheless, they all put great emphasis on the research methods associated with formal design theories: some papers underline the importance of models' consistency (Hatchuel et al.), or they rely on formal models as comparative framework for other theories (Le Masson & Weil, Shai et al., Kroll), or use theories as an analytical tool to study methods (Kroll, Kazakçi, Le Masson & Weil, Shai et al.). In this perspective, empirical research is used more as an illustration (eg Kroll or

Taura & Nagai). It is interesting to note that formal works can actually rely on multiple approaches. The formal models presented in these papers lead to insights that can be tested in empirical research: e.g the role of duality for concept generation in science discovery (Shai et al.), the relationship between industrial growth, new products and the generativity of design theories (Le Masson & Weil), the role of invariant ontology on generativity (Hatchuel et al.).

Summary: advances in Design Theory

Overcoming the four difficulties, the papers contribute to design theory by building, discussing, strengthening, or analyzing specific formal models. They help to understand the ecology of design theories, how each theory relates to specific logics and specific models of knowledge, and how, despite apparent differences, the design theories tend to share strong common points, i.e. following Hatchuel et al., tend to follow a *common ontology*.

Reading the six papers of this special issue, one can distinguish three “moments”. The first two papers, Le Masson & Weil and Kazakçi, help to *clarify some historical roots and paradigms in the field of design theory*. They explicate the relation between engineering science and the logic behind the historical variety of theories and methods in the field of engineering design (Le Masson & Weil) and the relation between constructivism and the paradigm of situated cognition (Kazakçi). Both papers pave the way to a *better understanding of the ontology of design*, which is the second moment of this special issue, mainly represented by the Hatchuel et al. paper. The third moment builds on the formal models today available to show how they help to analyze *critical issues for designers*: design and scientific discovery (Shai et al.), design and concept generation (Taura & Nagai) and design and the renewal of engineering rules (Kroll).

Reconnecting to the roots

In “Design theories as languages of the unknown: insights from the German roots of systematic design (1840-1960)”, Pascal Le Masson and Benoit Weil study the historical development of theories and methods. They focus on the particular case of German systematic design at three historical moments – 1840s and the industrial catch-up in Germany after the first industrial revolution; 1900s and the second industrial revolution; 1950s and the rationalization of intellectual work. Relying on the formal framework provided by C-K theory, they show that 1) historically, design theories and methods did not originate from either purely formal research or from descriptive studies of designer’s practices. They corresponded to specific rationalization of the design activity in historical context. 2) Contrary to engineering sciences, which model known objects, these theories are frameworks to guide the elaboration of still unknown objects with the help of available knowledge. They appear as more and more sophisticated languages of the unknown, whereas engineering models are languages of the known. These languages are progressively refined to reach new types of unknown. 3) These frameworks did not seek to cater for one-off innovation, but for the efficiency of design capacities. They analyze according to the types of new, partly unknown objects they help design (generative capacity) and the capacities required by their users (conjunctive capacity). The intention of these methods was to increase generative capacities while maintaining conjunctive capacity. Thus the paper works to overcome some issues in engineering design research: the difference with engineering science (language of the known vs. language of the unknown), the role of formal models to support the invention of methods (and the limits of descriptive models), and the ambition towards more generative theories. *Creation of the language of the unknown and generativity emerge as basic traits of design theory*.

In his paper entitled “on the imaginative constructivist nature of design”, Akin Kazakçi discusses constructivism in design. He reminds us that constructivism is one of the paradigms that has a great influence on design theory: interactive constructivism, and more broadly situated cognition, analyzed how the interactive media can influence design; social constructivism analyzed the effects of communication and social conventions and negotiations on the integration of individual expertise into the design process. To discuss this invading paradigm, Kazakçi uses the formal roots of constructivism, namely Brouwer’s intuitionism, which he analyzes with the lenses of formal design theory, C-K theory. He shows that intuitionism presents interesting notions for building design logics in mathematics (see the introduction of “incomplete” objects by means of lawless sequences and free choices). This formal design perspective reveals a logic of “imaginative” constructivism by Brouwer’s creative subject. While Brouwer’s creative subject is usually interpreted as a learning model relying on the combination of known objects, it is shown that the creative subject can also alter the bottom-up, combinative construction with the introduction of unexpected elements in order to construct objects with surprising properties - resulting in the expansion of the repertory of objects. Finally the paper suggests that in a design perspective, interactive constructivism should go beyond the analysis of shared representations to be able *to include ruptures in reasoning and the “presentation” of new objects*; and social constructivism should go beyond the understanding of trade-offs and negotiations *to include the creation of new values and interests through imaginative propositions*.

Some elements of an ontology of design

“Towards an ontology of design: lessons from C-K theory and Forcing” by Armand Hatchuel, Benoit Weil and Pascal Le Masson, aims at revealing an ontology of design by studying the similarities and differences between two of the most abstract formal theories of design, C-K theory in engineering design and Forcing in Set theory in mathematics. Two specific features can characterize formal design theories: domain independence and generativity. C-K theory is a good representative of the contemporary stage of abstraction and generativity in the field of engineering. As shown in the paper, the abstraction of Set theory makes that Forcing, a technique developed for the controlled invention of new models of sets, is a good representative of general design theories. The comparison reveals three common notions:

- 1) knowledge expandability is present in each case but it also appears that design theories are led to distinguish variable structures (or designed ontologies) and invariant structures (explicitly unchanged by design, like the Zermelo-Fraenkel axiomatic in models of set generated by Forcing);
- 2) knowledge “voids” are necessary for design, these are “independent structures” in existing knowledge, that are revealed when a proposition cannot be proved true or false with existing knowledge. The specific rationality of design is to “fill” the void to create a new desired thing;
- 3) Design needs generic processes for expansion, which include both the capacity to introduce new truths and revise the identity of objects and the capacity to re-order knowledge, to give new names and to preserve meaning.

Design theories for understanding critical issues in design

In “Design theory and conceptual design: contrasting functional decomposition and morphology with parameter analysis”, Kroll analyses a method, Parameter Analysis, to deal with innovative “conceptual design”. Whereas classical methods like functional analysis and morphological matrix (Zwicky 1969) tend to reuse existing design rules, with Parameter Analysis the designer focuses on the parameter that is considered as the most challenging

issue of the design brief and this helps him to quickly identify the areas where the renewal of design rules is most needed. Moreover, it prescribes a loop for creating the new design rules, based on “creative synthesis” and “evaluation”. Several cases illustrate how the method leads to renew design rules (Tilt-meter based on coupled pendulums, bilge pump and aerodynamic decelerators). Using C-K theory the paper shows that Parameter Analysis helps designer to organize an intense relationship between C and K, since each step of the Parameter Analysis process results in a C-expansion and a K-expansion; by contrast functional analysis and morphology appear as a form of search process limited to available knowledge. Further, the paper discusses some efficiency criteria for a design process: whereas many design methods tend to favor finding one solution that minimizes the creation of knowledge, Parameter Analysis focusses on *learning during* the design process while being able to meet the specifications. This dual capacity of Parameter Analysis to both meet the target and favor efficient learning makes it a promising method for educating young designers and for strategic use in industrial design processes.

In “A Systematized Theory of Creative Concept Generation in Design: First-order and high-order”, Toshiharu Taura and Yukari Nagai focus on the “concept generation” phase of a design process. In common view, this phase is said to be beyond the scope of “rational models”, a phase of “creative synthesis” as opposed to more “analytical” ones. Relying on specific illustrations and rigorous concept mapping, the authors show that concept generation can be analyzed as an intersection of “abstract concepts” – in the terminology of General Design Theory. The paper shows that there are actually two contrasted types of concept generation, first order and higher order one, the first one relying on an intersection based on similarity recognition (in the intersection, the designers “follows” a thematic relation), whereas the second one relies on *dissimilarity recognition*. General Design Theory helps to describe both processes but the problem solving approach embedded in GDT describes thematic relations and fails to account for dissimilarity recognition processes. The paper calls for an extension of GDT based on the notion of dissimilarity in the pre-design phase.

In “Creativity and scientific discovery with infused design and its analysis with C-K theory”, Offer Shai, Yoram Reich, Armand Hatchuel and Eswaran Subrahmanian address one of the key challenges for a design theory: modeling scientific discovery. In his “models of thought” (Simon 1979) and more precisely in (Simon and Kulkarni 1989), Simon faced the same challenge. Shai et al. go beyond Simon’s perspective to show how Infused Design helped to conceive a new force in physics, namely “face force”! Using C-K theory as an analytical tool, they show how scientific discovery relies on key aspects of a design reasoning:

- 1) There must be “holes” (the notion is similar to the “voids” in Hatchuel et al.) in knowledge. Further, infused design method is a powerful tool to *identify these holes*, by relying on strong knowledge structures across specific knowledge domains and by establishing, through duality relations, rigorous correspondences between these domains.
- 2) “Filling holes” is based on knowledge, and infused design helps to acquire new knowledge by correspondences with multiple domains (the design of “face force” in trusses is based on correspondences with mechanism and electrical circuits).
- 3) This knowledge propagation is done while preserving a consistency of the knowledge bases – and here again, infused design was instrumental in creating the “face force” that preserves the structures of knowledge domains.

Finally a design perspective on scientific discovery shows that the rigorous structure of scientific knowledge plays two critical roles in scientific discovery: it helps to identify “holes” and supports “consistent” expansions.

Concluding remarks: Design Theory and the science of design

This special issue brings to the reader a sample of works that illustrates the effort of a whole community, today, to renew its foundations. Following past (r)evolutions in design theory, it echoes trends in the new objects that have to be designed, trends in new forms of knowledge and knowledge production that have to be integrated in contemporary design processes and trends in other disciplines that are more and more linked to the design paradigm (like in past renewals, these design theories are linked to recent advances in many sciences – as diverse as mathematics, linguistic, engineering or even history).

Perhaps even more than in the past, the renewal of design theory should lead today to a body of *sustainable, collective research*. These papers show a good diversity and illustrate the constructive dialogue between multiple approaches. As a collection they help to make sense of the multiple formal models of design that exist today, and to integrate them in an ecology of theories. Finally, together they contribute to building a common language and create the capacity for fruitful discussions. As such, they hopefully provide a good basis for future advances on design theory and open the possibility of new forms of empirical research.

The renewal of design theory will help to *build a powerful discipline, a unified body of knowledge* that can engage with other disciplines on its own terms. External trends and paradigms then no longer threaten this unity but this unity helps to discuss and expand these paradigms to the test of the design perspective. One can hope that the formal models of design theory will in due course spark dialogues with sociology, economics, engineering sciences, or cognition to provide new paradigms for the research in those fields. More generally, they offer good foundations for further *formal* work as well as for an *open dialog* with other disciplines. They pave the way to an “open program” to discuss design theory and art, design theory and management, design theory and politics, design theory and users, and design theory and information systems.

In the broadest sense, the renewal of design theory should help to *understand and support contemporary forms of collective action*. The effort towards a clear design paradigm contributes to improving dialogue between the professions, recognizing their deep similarities. But looking far beyond these professional developments, we realize that our societies expect “innovative design” on major their challenges: in health, in smart cities, in sustainable energy, in smart mobility, in the autonomy of elderly people, in housing for everybody or in food... Recent advances in design theory might help to invent new forms of design action to address all these issues. These advances open the possibility to invent new methods, new organizations, and new forms of designerly collaborations inside and between organizations. These theories could provide the basic corpus and language to educate the designers of tomorrow in the logic of creation. And we need them as basic intellectual elements for life in contemporary societies that are entering the post-decisional paradigm – the design paradigm.
